1. Initial expectation

I came to this project with very open expectations. I wanted to do more applied work since I think a practical course offers unique learning opportunities. This is useful to me especially since I am completing my master's soon and I want to gain skills that I can also use in the workforce. Further, having an interesting project that is more than just coding also seems like a nice addition to my portfolio. I just wanted to see what would be possible with vibecoding, and ideally I would have liked to develop a project with actual impact.

2. Main learning

The most important learning for me was how to communicate with both people and also agents. It can be quite hard to convey your ideas to others, especially if they come with their own ideas or directions that they don't want to give up. Striking a balance here is difficult, and you not only need to be able to communicate what you want to do but also how, so that people and agents understand you precisely. Part of this is that for agents you also have to tell them exactly what to report, otherwise they often try to obfuscate what they are doing exactly and try to hide information. I think this hurts product quality a lot. Another benefit of thinking carefully about what you think is that you also develop your own ideas better and realize flaws or details where you yourself were unclear. Of course this is also a process of iteration.

3. Role and contribution in the group

I think our group worked pretty equally: whenever we had a dry phase, someone else picked up the baton. Max was more deeply into developing and technical parts, and Dominique focused more on testing and stepping back. I was less on the developing end but more interested in the marketing and user contribution part. I, for example, tried to offer the product to my circle and also created a survey to evaluate our final product. Also, I analyzed the feedback of professors. Of course I also contributed code (like improving the skill or adding DeepSeek to the app), but personally I have lost some interest in the technical part of coding, since this has substantially changed with LLMs — and if you are not as familiar with the app development topic (as I was at the time), then you are often in this weird place between kind of knowing and not really knowing what is going on. Therefore I found evaluating and testing the product much more interesting. Outside of the group I organized a discord server for the whole class and I at least tried to facilitate communication and support among the students. I also built the career-skill and published it on my repo, because I personally needed it and thought it would be useful to build from the learnings in this project. Overall I think the collaboration worked well, and I think this was also part of an interesting learning journey.

4. Future learning

What I would be interested in further would be more about testing products with customers and how to really get accurate data about this. Also, I want to learn how to solve this problem of guiding agents while not losing control and still knowing what is going on. My trust in coding agents, at least for something you care about (like a product or a scientific publication), is low. Yes, they are very capable (and I don't have the means for the best of the best models, perhaps), but they often make a lot of weird mistakes a human would not make, and this — at least for me — makes this problem unsolved. For frontend this is easy to iterate, but for bugfixes and logic I

think it is still good to retain some knowledge about your own code. If you think this further, there are parallels to alignment of agents too, a topic I think is also very interesting.
